User Interface Design

Users can log in to the POS system as administrator or cashier with the correct username and password. Admin can select to manage user and issue coupon. Meanwhile, cashier can scan barcode, view inventory system and handle return. Each module performs their responsible function independently without overlapping to others task. For example, Manage User Module can only crud users (view user, add user, delete user and update user information). It is isolated from sales operation. The system demonstrates low coupling with independence component, clear boundaries and minimal dependency. Admin Menu and Cashier Menu are separated, each performs its own tasks. In addition, data is flown by interface such as cashier modules pass only needed data (cashierID, productList and receiptID) without importing ManageUser. All method names align with class diagram and each user interface matches with their corresponding class. All selection actions follow a standardized uppercase title, numbering format and command design.
